How The Filtermist Unit Works

- The three phase motor rotates the drum at high RPM creating a vacuum and drawing the oilmist into the unit.
- The oil mist particles collide with the vanes of the rotating drum and coalesce into larger droplet sized particles.
- These larger droplets are forced through the perforations in the drum and by centrifugal force and impact on the inside of the outer casing.

- 4. The droplets are then forced up the inside wall of the casing to the return spigot where they are returned to the machine.
- 5. Clean air is exhausted through the top of the unit back into the shop.
- 6. A dry smoke afterfilter can be fit over top of the motor as an option for applications that require it.
